Let's see how great a concern it should be if we use a median instead of an average for the altitudes and the time. Just by coincidence, exactly one year ago I took two series of nine shots each with my A-7 bubble octant to check its index error.

Here is the data:
May 7, 2011. A.P. $34^{\circ} 16.6^{\prime} \mathrm{N}, 118^{\circ} 54.0^{\prime}$ W. Center of the sun.

| $23: 46: 00$ | $35^{\circ} 17^{\prime}$ |
| ---: | ---: |
| 14 | 06 |
| 29 | 09 |
| 43 | 08 |
| 59 | 06 |
| $47: 15$ | 02 |
| 28 | 01 |
| 40 | $34^{\circ} 58$ |
| 58 | 52 |
|  |  |
|  |  |
|  |  |
|  |  |
| $23: 48: 18$ | $34^{\circ} 51^{\prime}$ |
| 31 | 48 |
| 46 | 47 |
| $49: 04$ | 41 |
| 21 | 39 |
| 37 | 33 |
| 51 | 33 |
| $50: 09$ | 27 |
| 21 | 25 |

The first series took 1:58 so the median time was 23:46:59 while the average time for the series was 23:46:58.4, a 0.6 seconds difference. The median altitude was 3506 ' while the average altitude was 3504.3 ' a difference of 1.7'. Using the median time with the median altitude produced an intercept of 0.4 T ; median time with average altitude $=1.3 \mathrm{~A}$; average time with median altitude $=0.2 \mathrm{~T}$; average time with average altitude $=1.5 \mathrm{~A}$ so the maximum difference was 1.9 NM .

The second series took 2:03 so the median time was 23:49:20 while the average time for the series was 23:49:19.8, a 0.2 seconds difference. The median altitude was $34^{\circ} 39^{\prime}$ while the average altitude was $34^{\circ} 38.2^{\prime}$ a difference of $0.8^{\prime}$. Using the median time with the median altitude produced an intercept of 2.4 T ; median time with average altitude $=1.6 \mathrm{~T}$; average time with median altitude $=2.4 \mathrm{~T}$; average time with average altitude $=1.6 \mathrm{~T}$ so the maximum difference was 0.8 NM.

If we combine both series into one 18 shot set then the total series took $4: 21$ so the median time was 23:48:10.5 while the average time for the series was $23: 48: 20.2$, a 9.7 seconds difference. The median altitude was $34^{\circ} 51.5^{\prime}$ while the average altitude was $34^{\circ} 51.3^{\prime}$ a difference of $0.2^{\prime}$. Using the median time with the median altitude produced an intercept of 0.5 T ; median time with average altitude $=0.3 \mathrm{~T}$; average time with median altitude $=2.6 \mathrm{~T}$; average time with average altitude $=2.4 \mathrm{~T}$ so the maximum difference was 2.3 NM .
