## Conditions for Positive Altitudes in Bygrave/MHR1 Calculations

In general for an observer at latitude, $L$, the altitude, $h$, of a celestial body with declination, $\delta$, and local hour angle, LHA, is given by

$$
\sin h=\sin \delta \sin L+\cos \delta \cos L \cos \mathrm{LHA}
$$

From this it follows that the object is on the horizon $(h=0)$ when

$$
\cot \left(90^{\circ}-L\right)=-\cot \delta \cos \mathrm{LHA}
$$

But ignoring the minus sign this is just the calculation used in the procedure for finding y in the Bygrave instructions ( x in the MHR1). So y represents the limiting colatitude at which a celestial body of given declination and altitude is just on the horizon.

By considering the various possible combinations of parameters it is found that the altitude obtained from using a Bygrave or MHR1 is positive (i.e. above the horizon or zenithal distance $\mathrm{ZD}<90^{\circ}$ ) if and only if any one of three conditions is satisfied

## Bygrave Notation

| $\mathbf{L}$ and $\mathbf{d}$ | $\mathbf{H}$ | c and $\mathbf{y}$ |
| :---: | :---: | :---: |
| same name | less than $90^{\circ}$ | No restriction |
|  | greater than $90^{\circ}$ | $\mathrm{Y}=\mathrm{c}+\mathrm{y}$ less than $180^{\circ}$ |
| contrary name | less than $90^{\circ}$ | c greater than y |

## MHR1 Notation

| $\boldsymbol{\varphi}$ and $\boldsymbol{\delta}$ | $\mathbf{t}$ | b and $\mathbf{x}$ |
| :---: | :---: | :---: |
| same name | less than $90^{\circ}$ | No restriction |
|  | greater than $90^{\circ}$ | $\mathrm{y}=\mathrm{b}+\mathrm{x}$ less than $180^{\circ}$ |
| contrary name | less than $90^{\circ}$ | b greater than x |

| $\boldsymbol{\varphi}$ und $\boldsymbol{\delta}$ | $\mathbf{t}$ | b und $\mathbf{x}$ |
| :---: | :---: | :---: |
| gleichnamig | kleiner $90^{\circ}$ | keine Einschränkung |
|  | größer $90^{\circ}$ | $\mathrm{y}=\mathrm{b}+\mathrm{x}$ kleiner $180^{\circ}$ |
| ungleichnamig | kleiner $90^{\circ}$ | b größer x |

The conditions look asymmetric due to the practice of not retaining signs in the Bygrave/MHR1 calculations. Subtractions always produce positive values. It also uses the convention that the hour angle falls in the range $0^{\circ}$ to $180^{\circ}$ and is qualified as being E or W rather than a value in the range $0^{\circ}$ to $360^{\circ}$ as is common practice today. In more modern notation and assuming the sign in the Bygrave variable Y (MHR1 variable y) was kept these conditions can be written

| L and d | $\boldsymbol{\operatorname { c o s }}(\mathbf{H})$ | $\mathbf{Y}$ |
| :---: | :---: | :---: |
| same sign | + | No restriction |
|  | - | $\mathrm{Y}<180^{\circ}$ |
| opposite sign | + | $\mathrm{Y}>0^{\circ}$ |
